Some important terms, concepts and formulae

- 1. Amines are alkyl or aryl derivatives of ammonia.
- 2. Amines can be prepared by (i) ammonolysis of alkyl halides, (ii) reduction of nitrocompounds (iii) reduction of cyanide, amide and oximes, (iv) Reduction amination of aldehydes/Ketones.
- Reaction of an amide with Br2 in presence of NaOH to give a primary amine 3. which has one C-atom less than parent amide is called Hoffmann's bromamide reaction.
- Aliphatic amines are soluble in water but aromatic amines are insoluble. 4.
- Boiling point of amines are higher than alkanes but lower than carboxylic 5.
- The basic strength of different degree of amines is: 6.

2° > 1° > 3° in aquous medium and

 $3^{\circ} > 2^{\circ} > 1^{\circ}$ in non-aquous medium.

- Aromatic amines are weaker base than aliphatic amines. 7.
- Electron releasing groups like CH₃, OCH₃, NH₂ etc. increase the basic 8. strength while electron withdrawing groups like - NO₂, - CN etc. decreases the basic strength of aniline. The effect of these substituents is more at pposition and less at o-position.
- Ortho substituted aniline are weaker bases than aniline irrespective of electron 9. releasing or attracting effect of the substituent. This is referred so as ortho
- Aniline reacts with HNO₂ at 0-5°C to give benzene diazonium chloride. 10.
- -NH₂ group in aniline is ring activating and ortho-, para-directing group. 11. 12.
- 1°, 2° and 3° amines can be distinguished by Hoffmann's method.

flead the above mentioned various definitions, explanations and official following the solved examples, try to solve the other similar questions independently.

5.1 Aliphatic amines

very Short Questions-Answers

1. Write down any two methods of preparation of aliphatic amines.

Ans: Aliphatic amines can be prepared as:

(a) By ammonolysis: Alkyl halide reacts with ammonia to form primary, secondary and tertiary amines. If ammonia is used in excess, primary amine is the major product.

$$C_2H_5 - Br + 2 NH_3 \text{ (excess)} \longrightarrow C_2H_5NH_2 + NH_4Br$$

Bromoethane ethanamine

If alkyl halide is in excess, the primary amine formed further reacts with alkyl halide to form secondary amine, tertiary amine and finally quarternary ammonium salt.

$$\begin{array}{c} \text{CH}_3-\text{CH}_2-\text{NH}_2 \xrightarrow{C_2 \text{H}_5 \text{Br}} & \text{C}_2 \text{H}_5 \\ \hline C_2 \text{H}_5 & \text{NH} \xrightarrow{C_2 \text{H}_5 \text{Br}} & \text{C}_2 \text{H}_5 \\ \hline C_2 \text{H}_5 & \text{C}_2 \text{H}_5 & \text{Tertiary amine} \\ \hline C_2 \text{H}_5 \text{Br} & \text{C}_2 \text{H}_5 \\ \hline C_2 \text{H}_5 - \text{N} - \text{C}_2 \text{H}_5 \\ \hline C_2 \text{H}_5 & \text{C}_2 \text{H}_5 \\ \hline \end{array}$$

Tetraethyl ammonium bromide

(b) By reduction of alkyl cyanides: The alkyl cyanides on reduction with H₂/Ni, LiAlH₄ or Na/C₂H₅OH give primary amines.

$$CH_3 - CN + 4H \xrightarrow{LiAlH_4} CH_3 - CH_2 - NH_2$$
Ethanenitrile

Ethanamine

Q2. Give the action of ethanamide with (a) LiAlH4 and (b) Br2/KOH.

Ans: (a) LiAlH₄: Ethanamide is reduced by LiAlH₄ into ethanamine.

CH₃-C-NH₂ + 4[H]
$$\xrightarrow{\text{LiAlH}_4}$$
 CH₃-CH₂ - NH₂ + H₂O Ethanamine

(b) Br₂/KOH: Ethanamide gives methanamine when heated with bromine in the presence of alkali at about 70°C. This reaction is also known as Hoffmann's - bromamide reaction.

$$\begin{array}{c} O \\ CH_3-C-NH_2 + Br_2 + 4KOH \\ \hline \\ Ethanamide \\ \end{array} \begin{array}{c} 70^{\circ}C \\ \hline \\ CH_3-NH_2 + 2KBr + K_2CO_3 + 2H_2O \\ \hline \\ \end{array}$$

Scanned with CamScann

Q.3. How does ethanamine reacts with (a) CHCl₃/KOH and (b) CH₃-C₋Cl₂

Ans: (a) CHCl₃/KOH: When ethanamine is reacted with chloroform (CHCl₃) in presence of a base, ethylcarbylamine is obtained.

presence of a base, each $\frac{\text{KOH}}{\text{CH}_3 - \text{CH}_2 - \text{N}} = \frac{\text{C}_1 + 3\text{KC}_1 + 3\text{H}_20}{\text{Ethanamine}}$ Ethanamine

(b) CH₃-C -Cl: On the otherhand, ethanamine reacts with ethanoylchloride to give N-ethylethanamide.

 $\begin{array}{c} O \\ \parallel \\ CH_3-CH_2-NH_2 + CH_3-C-Cl \longrightarrow CH_3-CH_2-NH-C-CH_3+HCl \\ \hline Ethanamine & Ethanoylchloride & N-ethylethanamide \\ \end{array}$

Q.4. What happens when ethanamine is reacted with NaNO₂ in presence of HCl below 5°C?

Ans: NaNO2 reacts with HCl below 5°C to give nitrous acid.

 $NaNO_2 + HC1 \longrightarrow NaCl + HNO_2$

Nitrous acid

The nitrous acid thus obtained reacts with ethanamine to give ethanol and $\rm N_{\rm 2}$ gas.

 $CH_3 - CH_2 - NH_2 + HNO_2 \longrightarrow CH_3 - CH_2 - OH + N_2 \uparrow + H_2O$ ethanamine Ethanol

Q.5. Why is methylamine more basic than aniline?

Ans: Let us see the structures of aniline and methylamine.

$$\begin{array}{c}
\ddot{N}H_2 \\
\vdots \\
CH_3 \rightarrow NH_2 \\
methylamine
\end{array}$$

Both in aniline and methylamine, N-atoms have a lone-pair of electrons as shown above.

Aromatic ring in aniline is electron-withdrawing. The lone-pair on N-atom in aniline is less available for donation to H⁺ (i.e. for protonation) because the lone-pair is delocalised mostly into the benzene ring by resonance. Thus, aniline is less basic.

$$\stackrel{: NH_2}{\longleftrightarrow} \stackrel{: NH_2}{\longleftrightarrow} \stackrel{+ NH_2}{\longleftrightarrow} \stackrel{: NH_2}{\longleftrightarrow} \stackrel{: NH_2}{\longleftrightarrow} \stackrel{: NH_2}{\longleftrightarrow}$$

Fig.: resonance structures of aniline

In methylamine, the lone-pair of electrons does not participate in resonance. Furthermore, -CH₃ group in methylamine releases electron on N atom and it consequently increases the electron density on N-atom by +1 effect. Therefore, the lone-pair on N-atom is more available for protonation. The greater the tendency to donate the lone-pair, the more basic would be the compound. Thus, methylamine is more basic than aniline.

Short Questions-Answers

Describe the method of separation of 1°, 2° and 3° amines from their

To separate 1°, 2° and 3° amines from its mixture by Hoffmann's method, diethyl oxalate is added to the mixture, where different degree of amines react differently with diethyl oxalate to give different products.

The primary amine reacts with diethyl oxalate to give solid

The secondary amine gives a liquid dialkyloxamic ester. (ii)

$$R_2NH + COOC_2H_5 \longrightarrow CONR_2 + C_2H_5OH$$
 $COOC_2H_5 \longrightarrow COOC_2H_5$
 $COOC_2H_5 \longrightarrow COOC_2H_5$

The tertiary amine does not react with diethyloxalate. (iii)

After this, the mixture containing all the products diethyl oxamide, dialkyl oxamic ester, alcohol and the reagents tertiary amine is first filtered to separate out the solid oxamide. It is obtained as residue, which is then heated with KOH to recover primary amine.

The filtrate is then subjected to fractional distillation when the tertiary amine distills over first followed by alcohol. At last, the residual oxamic ester is treated with aquous KOH and distilled fractionally to get secondary amine and alcohol in different fractions.

$$\begin{array}{c} \text{CONR}_2 \\ \text{COOC}_2\text{H5}_2 \end{array} + 2 \text{ KOH} \longrightarrow \begin{array}{c} \text{COOK} \\ \text{COOK} \end{array} + \begin{array}{c} \text{R}_2\text{NH} + \text{C}_2\text{H}_5\text{OH} \\ \text{2° amine} \end{array}$$

This method of separation of 1°, 2° and 3° amine is known as Hoffmann's method.

17. Discuss the following basicity order of different degree of amines:

2° amine > 1° amine > 3° amine. We know that alkyl amines are more basic than ammonia because alkyl groups are electron releasing groups which increases the electron density on nitrogen atom by +I effect. This effect makes the lone pair more easily available on N-atom and hence makes it more basic. If we treat the basicity on this sole effect we will obtain the following order.

$$\begin{array}{c|c} CH_3 & CH_3 \\ CH_3 & CH_3 & CH_3 & CH_3 \\ CH_3 & H & 1^{\circ} \text{ amine} \\ 3^{\circ} \text{ amine} & 2^{\circ} \text{ amine} \end{array}$$

As 3° amine has three electron releasing groups, 2° has only two and 1° has only one.

However it is not so. In fact the basic strength in aquous solution depends not only upon electron releasing effect but also upon steric effect and hydration effect.

- hydration effect.

 (a) Steric effect refers to the crowding of alkyl groups around N-atom which hinders the attack of proton on the amine molecule and thus, decreases its basic strength. Since, crowding of alkyl groups around N-atom increased from primary to tertiary amines, consequently the basic strength of amine should decrease, in the order 1° > 2° > 3°.
- (b) Hydration effect refers to the stabilization of the protonated amine by the water molecules. The water molecules form H-bonds with protonated amine and release energy called hydration energy. Now greater the extent of H-bonding in protonated amine more will be its strength of the corresponding amine. The order of hydration is $1^{\circ} > 2^{\circ} > 3^{\circ}$.

Therefore, basic strength should decrease from $1^{\circ} > 2^{\circ} > 3^{\circ}$. But, we find that in 3° amine hydration is least and steric hindrance is maximum. Thus, it is least basic in spite of maximum +I effect. In 1° amine steric hindrance is least hydration is maximum and +I effect is also minimum. Hence, its basic strength is more than 3° amine but less than 2° amine. The resultant of all factors cause 2° amine to be still more basic than 1° amine. Thus, over all basic strength varies as: $2^{\circ} > 1^{\circ} > 3^{\circ}$.

Q.8. Carry out the following conversions: Methanamine to ethanamine and vice-versa.

Ans: Methanamine can be converted into ethanamine as follows:

$$\begin{array}{c} \text{CH}_{3}\text{-}\text{NH}_{2} \xrightarrow{\text{NaNO}_{2}/\text{HCl}} \text{CH}_{3}\text{-}\text{O} - \text{N} = \text{O} \xrightarrow{\text{NaOH}} \begin{array}{c} \text{NaOH} \\ \text{NaNO}_{2} \end{array} \xrightarrow{\text{CH}_{3}\text{-}\text{OH}} \begin{array}{c} \text{PI}_{3}/\Delta \\ \text{Methanol} \end{array} \xrightarrow{\text{CH}_{3}\text{-}\text{I}} \begin{array}{c} \text{Iodomethane} \\ \text{NaCN} \end{array}$$

Similarly, ethanamine can be converted into methanamine by the following reaction sequence given below:

$$\begin{array}{c} \text{CH}_{3}\text{-}\text{CH}_{2}\text{-}\text{NH}_{2} \\ \text{Bhanamine} \end{array} \xrightarrow{\begin{array}{c} \text{NaNO}_{2}/\text{HCl} \\ \text{Ethanol} \end{array}} \begin{array}{c} \text{CH}_{3}\text{-}\text{CH}_{2}\text{-}\text{OH} \\ \text{Ethanol} \end{array} \xrightarrow{\begin{array}{c} \text{K}_{2}\text{Cr}_{2}\text{O}_{7}/\text{H} + \\ \text{CH}_{3}\text{-}\text{C}\text{-}\text{OH} \\ \text{Ethanoic acid} \\ \downarrow \text{SOCl}_{2} \end{array}$$

15.2 Aromatic amine

very Short Questions-Answers

Q.1. What happens when benzamide is heated with bromine in presence of NaOH?

Ans: Aniline is obtained as the product.

$$O \longrightarrow NH_2$$

$$+ Br_2 + 4NaOH \longrightarrow O$$

$$+ 2NaBr + Na_2CO_3 + 2H_2O$$

Benzamide

Aniline

Q.2. What is carbylamine reaction?

Ans: It is a method to detect primary amine in laboratory. When a primary amine is warmed with chloroform and alcoholic potassium hydroxide solution, an alkyl isocyanide or carbylamine with offensive smell is obtained. The generation of offensive smell confirms primary amine. e.g.

$$C_2H_5 - NH_2 + CHCl_3 + 3 KOH \rightarrow C_2H_5 - N \stackrel{\blacktriangle}{=} C + 3 KCl + 3 H_2O$$

Ethanamine chloroform ethyl isocyanide

 $O \longrightarrow NH_2 + CHCl_3 + 3 KOH \longrightarrow O \longrightarrow N \stackrel{\blacktriangle}{=} C + 3 KCl + 3 H_2O$

$$\bigcirc$$
 NH₂ + CHCl₃ + 3 KOH \bigcirc N $\stackrel{\triangleright}{=}$ C + Chloroform Phenylisocyanide

Q.3. What happens when

(a) Aniline is shaken well with aquous bromine?.

(b) Aniline is reacted with acetaldehyde in acidic medium?

Ans: (a) Benzene ring in aniline is highly activated due to presence of electron donating amine group. So, when it is reacted with aquous bromine, 2,4,6-tribromo aniline is obtained.

2,4,6-tribromoaniline

(b) When aniline is reacted with acetaldehyde in slightly acidic medium, a Schiff's base is obtained.

On
$$H_2 + H - C - CH_3$$
Aniline

ON $H_2 + H - C - CH_3$
Acetaldehyde

A Schiff's base

Q.4. Give an example of diazotization reaction.

Ans: When primary amine such as aniline is treated with ice cold solution of NaNO₂ in the presence of ice cold solution of dil. HCl (i.e., at 0-5°C), diazonium salt is produced. Thus, introduction of N₂⁺Cl⁻ group in benzene ring is known as diazotisation reaction.

$$\begin{array}{c|c}
 & \text{NH}_2 \\
 & \text{N}_2 \\
 & \text{N}$$

Q.5. What is Schotten-Baumann reaction?

Ans: Acylation of alcohol or amine by the action of acid chloride in the aquous alkaline solution is known as Schotten-Baumann reaction. i.e.

$$\begin{array}{c} \text{NH}_2 \\ \\ \text{NH} - \text{C} - \text{CH}_3 \\ \\ \text{Aniline} \end{array} + \begin{array}{c} \text{NH} - \text{C} - \text{CH}_3 \\ \\ \text{N-phenylacetamide} \end{array} + \begin{array}{c} \text{NaCl} + \text{H}_2\text{O} \\ \\ \text{N-phenylacetamide} \end{array}$$

Short Questions-Answers

Q.6. What are the products obtained when aniline reacts with (a) Conc. H₂SO₄ (b) acidified K₂Cr₂O₇ (c) NaNO₂/HCl.

How will you convert aniline into phenol?

Ans: (a) Conc. H₂SO₄: Aniline reacts with conc. H₂SO₄ to give sulphanilic acid

NH₂

$$+ \text{ Conc. H}_2\text{SO}_4 \xrightarrow{180^{\circ}} \text{NH}_2$$
Aniline
$$+ \text{ SO}_3\text{H}$$
Sulphanilic acid

(b) acidified K₂Cr₂O₇: Aniline is oxidized by acidified K₂Cr₂O₇ into benzoquinone

$$\begin{array}{c}
NH_2 \\
\hline
O \\
Aniline
\end{array}
+ [O] \xrightarrow{K_2Cr_2O_7/H+}
\begin{array}{c}
O \\
O \\
O \\
Benzoquinone
\end{array}$$

(c) NaNO₂/HCl: aniline reacts with NaNO₂ in presence of HCl below 5°C to give benzene diazonium chloride.

$$NH_2$$
 $+ NaNO_2 + HCl$
 $+ H_2O$

Aniline

Benzene diazonium chloride

Aniline can be converted into phenol as follows:

$$\begin{array}{c|c}
NH_2 & \bullet N \equiv N \text{ Cl} & OH \\
\hline
NaNO_2/HCl & H_2O/H^+ & + N_2^+ + HCl \\
Aniline & Phenol
\end{array}$$
